Chapter 1

Basic Properties of Numbers

1.1.

- (i) Suppose that $ax = a$ and $a \neq 0$, then there exists a number a^{-1} . Multiplying a^{-1} on both sides yields

$$\begin{aligned}(a^{-1}a) \cdot x &= a^{-1}a \\ x &= 1\end{aligned}$$

as desired.

- (ii) We use the distributive property on $(x - y)(x + y)$, this can be done by letting $a = x - y$:

$$\begin{aligned}(x - y)(x + y) &= a(x + y) \\ &= ax + ay = (x - y)x + (x - y)y \\ &= x^2 - yx + xy - y^2 = x^2 - y^2\end{aligned}$$

- (iii) If we have $x^2 = y^2$ then we certainly have $x^2 - y^2 = 0$. By (ii) we know that $0 = (x - y)(x + y)$, this implies that $x - y = 0$ or $x + y = 0$, this is equivalent to saying that $x = y$ or $x = -y$.

- (iv) Same method as (ii):

$$\begin{aligned}a(x^2 + xy + y^2) &= ax^2 + axy + ay^2 \\ &= (x - y)x^2 + (x - y)xy + (x - y)y^2 \\ &= x^3 - yx^2 + x^2y - xy^2 + xy^2 - y^3 \\ &= x^3 - y^3\end{aligned}$$

- (v) We prove this by induction, the base case $n = 2$ is already proven in (ii). Suppose $x^n - y^n = (x - y)(x^{n-1} + x^{n-2}y + \cdots + xy^{n-2} + y^{n-1})$ is true. Then we equivalently have $x^n = (x - y)(x^{n-1} + x^{n-2}y + \cdots + xy^{n-2} + y^{n-1}) + y^n$. We now prove the $n+1$ case:

$$\begin{aligned}
 x^{n+1} - y^{n+1} &= x \cdot x^n - y^{n+1} \\
 &= x(x - y)(x^{n-1} + x^{n-2}y + \cdots + xy^{n-2} + y^{n-1}) + xy^n - y^{n+1} \\
 &= (x - y)(x^n + x^{n-1}y + \cdots + x^2y^{n-2} + xy^{n-1}) + (x - y)y^n \\
 &= (x - y)(x^n + x^{n-1}y + \cdots + xy^{n-1} + y^n)
 \end{aligned}$$

The resulting relation concludes the finite induction, thus $x^n - y^n = (x - y)(x^{n-1} + x^{n-2}y + \cdots + xy^{n-2} + y^{n-1})$.

- (vi) We know from (iv) that $a^3 - b^3 = (a - b)(a^2 + ab + b^2)$, by letting $a = x$ and $b = -y$ we get $x^3 + y^3 = (x + y)(x^2 - xy + y^2)$.

1.2. Multiplying by the multiplicative inverse of $x - y$ works only when $x - y \neq 0$, that is $x \neq y$, however, the hypothesis explicitly states $x = y$. So it is not possible to find the multiplicative inverse of $x - y$ and thus the step is invalid.

1.3.

- (i) Say we have $\frac{a}{b}$ and $b \neq 0$ then the same fraction can be written as ab^{-1} . Suppose we also have a variable c such that $c \neq 0$, then we have $ab^{-1} \cdot (cc^{-1})$ and consequently $(ac)(b^{-1}c^{-1}) = \frac{ac}{bc}$. The final equality holds by (iii) which is proven below.
- (ii) By (i) $\frac{ad}{bd} + \frac{bc}{db} = ad(bd)^{-1} + bc(bd)^{-1} = (ad + bc)(bd)^{-1} = \frac{ad+bc}{bd}$
- (iii) ab exists if $a, b \neq 0$. Let $x = (ab)^{-1}$, then

$$\begin{aligned}
 x(ab) &= (ab)^{-1}(ab) = (xa)b = 1 && \text{(Multiply } x \text{ with } ab) \\
 (xa)(bb^{-1}) &= b^{-1} = xa = b^{-1} && \text{(Multiply by } b^{-1}) \\
 x(aa^{-1}) &= b^{-1}a^{-1} = x && \text{(Multiply by } a^{-1})
 \end{aligned}$$

- (iv) Suppose $b, d \neq 0$, then $\frac{a}{b} \cdot \frac{c}{d} = (ab^{-1}) \cdot (cd^{-1}) = (ac)(b^{-1}d^{-1}) = (ac)(bd)^{-1} = \frac{ac}{bd}$

- (v) Suppose $b, c, d \neq 0$, then $\frac{a}{b} / \frac{c}{d} = (ab^{-1})(cd^{-1})^{-1} = (ab^{-1})(c^{-1}d) = (ac)(bd)^{-1} = \frac{ac}{bd}$
- (vi) Suppose $b, d \neq 0$. Assume $\frac{a}{b} = \frac{c}{d}$, multiplying by bd on both side yields the relation $ad = bc$. For the converse multiply $ad = bc$ by $(bd)^{-1}$.

1.4.

- (i) $4 - x < 3 - 2x \iff (4 - 4) + (-x + 2x) < (3 - 4) + (2x - 2x) \iff x < -1$.
- (ii) $5 - x^2 < 8 \iff -3 < x^2$. Note that $x^2 \geq 0$ and for every single value of x , so our solution is every x .
- (iii) $5 - x^2 < -2 \iff 7 < x^2 \iff \sqrt{7} < x \text{ or } -\sqrt{7} > x$.
- (iv) The product is positive when $x - 1 > 0$ and $x - 3 > 0$ or when $x - 1 < 0$ and $x - 3 < 0$, that is when $x > 3$ or when $x < 1$.
- (v) Complete the square $x^2 - 2x + 2 = (x - 1)^2 + 1$. The product $(x - 1)^2$ is always positive, and since we have the $+1$ as well in the inequality, this inequality must be true for every single x .
- (vi) The inequality is equivalent to $x^2 + x - 1 > 0$. Completing the square $(x + \frac{1}{2})^2 > \frac{5}{4}$. If $x \geq -\frac{1}{2}$ then $x > \frac{-1+\sqrt{5}}{2}$. If $x < -\frac{1}{2}$ then $x < \frac{-1-\sqrt{5}}{2}$. Thus, the solution is $x > \frac{-1+\sqrt{5}}{2}$ and $x < \frac{-1-\sqrt{5}}{2}$.
- (vii) Equivalently we have $(x - \frac{1}{2})^2 > \frac{25}{4}$. If $x \geq \frac{1}{2}$ then $x > 3$ if $x < \frac{1}{2}$ then $x < -2$. The solution set is $x > 3$ and $x < -2$.
- (viii) Equivalently $(x + \frac{1}{2})^2 + \frac{3}{4} > 0$. This is true for every x because $(x + \frac{1}{2})^2 \geq 0$ and $\frac{3}{4} > 0$. Adding them gives $(x + \frac{1}{2})^2 + \frac{3}{4} > 0$.
- (ix) Let $b = (x + 5)(x - 3)$. Then b is positive if $x > 3$ or $x < -5$ and negative if $-5 < x < 3$. Let $a = x - \pi$. a is positive if $x > \pi$. ab is positive if both a and b are positive or if both are negative. So ab is positive if $x > \pi$ (b must be positive because $x > 3$). ab is negative if $-5 < x < 3$ (This implies $x < \pi$).

- (x) If $x > \sqrt[3]{2}$ and $x > \sqrt{2}$ then the product is positive, thus the first solution is $x > \sqrt{2}$. If $x < \sqrt[3]{2}$ and $x < \sqrt{2}$ then the product is positive. The second solution is $x < \sqrt[3]{2}$.
- (xi) Apply \log_2 on both sides: $x < 3$.
- (xii) Suppose $x < 1$, we will show this is a solution. We have $3^x < 3^1 = 3$, adding $x < 1$ to the inequality we get $x + 3^x < 3 + 1 = 4$. Since both 3^x and x are strictly increasing expressions finding the inequality $x < 1$ suffices as all real solutions.
- (xiii) Noting that $x \neq 0$ and $x \neq 1$. Expanding the fractions we get $\frac{1-x}{x(1-x)} + \frac{x}{x(1-x)} = \frac{1}{x(1-x)} > 0$. The solutions depends on if the denominator is positive. Thus $x(1-x) > 0$ has the same solution set. The solutions are $0 < x < 1$.
- (xiv) Note $x \neq -1$. Expand by $(x+1)$: $\frac{(x-1)(x+1)}{(x+1)^2} > 0$. Since the denominator is always positive we can multiply this on both sides, $x^2 - 1 > 0$, Thus $x < -1$ and $x > 1$.

1.5.

- (i) Suppose $a < b$ and $c < d$ then we have $b - a > 0$ and $d - c > 0$ by property 11 $(b - a) + (d - c) > 0$ which is the same as $b + d > a + c$.
- (ii) Suppose $a < b$ then $0 < b - a \iff -b < (b - b) - a = -b < -a$.
- (iii) Suppose $a < b$ and $c < d$, by (ii): $-c < -d$, then by (i) we have $a - d < b - d$.
- (iv) Suppose $a < b$ then $b - a > 0$. Assume $c > 0$, Using (P12) we know that $c(b - a) > 0$ and consequently $bc - ac > 0 \iff bc > ac$.
- (v) Suppose $a < b$ then $b - a > 0$. Assume $c < 0$, then by (ii) we have $-c > 0$. Using P12 we know that $-c(b - a) > 0$ and consequently $ac - bc > 0 \iff ac > bc$.
- (vi) Since $a > 1 > 0$ we apply (iv) by letting $c = a$. Thus $a^2 > a$.
- (vii) Because a is positive, it follows by applying (iv) to $a < 1$ that $a^2 < a$.

- (viii) Using (iv), multiply $a < b$ with c and $c < d$ with b . This means that we have $ac < bc$ and $bc < bd$, this is the same as $ac < bc < bd$, thus $ac < bd$.
- (ix) Using (viii) we multiply the same inequality twice, $a^2 < b^2$
- (x) Suppose $a, b \geq 0$, we prove the contra-positive, therefore $a \geq b$. Multiply by a and b respectively gives two inequalities $a^2 \geq ab$ and $ab \geq b^2$ which is the same as $a^2 \geq ab \geq b^2$. This concludes the contra-positive proof because $a^2 \geq b^2$ is the logical opposite of $a^2 < b^2$

1.6.

- (a) The base case is $n = 2$ which was proven in problem 1.5. Assume $x^n < y^n$ for $0 \leq x < y$. By (viii) we have $x \cdot x^n < y \cdot y^n \iff x^{n+1} < y^{n+1}$. The induction is complete, thus if $0 \leq x, y$ then $x^n < y^n$ for $n = 1, 2, \dots$
- (b) Suppose $x < y$, let the base case be $n = 3$
